# Binary search on arrays

In the lecture, we learned binary search, and we want you to implement the binary search. It is a very efficient algorithm, and it will not only used on arrays..

Anyway, in this problem, you are given an integer array a[1..n] and m integers  $x_1, x_2, \dots, x_m$  that we need to search from this array. The elements on the array are distinct. For each  $x_i$ , please find whether  $x_i$  exists in the array a or not.

To reject solutions that read all  $x_1, x_2, \dots, x_m$  and compute answers at once, we decided to give inputs in a different way. Please refer to the input format and notes for further information.

## Input

Your input consists of an arbitrary number of records, but no more than 5.

Each record starts with a line containing two integers n and m ( $1 \le n, m \le 100,000$ ), the number of integers. The next line contains n distinct integers  $a[1], a[2], \cdots, a[n]$  ( $0 \le a[i] < 10^9$ ), which are the elements of the array. The next line contains  $y_1, y_2, \cdots, y_m$  ( $0 \le y_j < 10^9$ ), which are used to generate the sequence  $x_1, x_2, \cdots, x_m$ . You should generate like this:

- $\bullet \quad x_1 = y_1.$
- For all  $j \ge 2$ ,  $x_j = (x_{j-1} + y_j) \mod 10^9$  if  $x_{j-1}$  exists in array a, and  $x_j = (x_{j-1} y_j) \mod 10^9$  otherwise.

The end of input is indicated by a line containing only the value -1.

#### **Output**

For each input record, print a line that contains m digits. The j-th  $(1 \le j \le m)$  digit should be '1' if  $x_j$  exists in array  $a_j$  and '0' otherwise.

## **Example**

Standard input	Standard output
3 6	111010
1 3 2	01101
1 1 1 1 1 1	
3 5	
3 5 1	
2 1 2 -1 -3	
-1	

#### **Notes**

For the first sample:

- $x_1 = y_1 = 1$ . 1 exists in array a.
- $x_2 = x_1 + y_2 = (1+1) \mod 10^9 = 2$ . 2 exists in array a.
- $x_3 = x_2 + y_3 = (2+1) \mod 10^9 = 3$ . 3 exists in array a.
- $x_4 = x_3 + y_4 = (3 + 1) \mod 10^9 = 4$ . 4 doesn't exist in array a.
- $x_5 = x_4 y_5 = (4 1) \mod 10^9 = 3$ . 3 exists in array a.
- $x_6 = x_5 + y_6 = (3+1) \mod 10^9 = 4$ . 4 doesn't exist in array a.

For the second example:

- $x_1 = y_1 = 2$ . 2 doesn't exist in array a.
- $x_2 = x_1 + y_2 = (2 1) \mod 10^9 = 1$ . 1 exists in array a.
- $x_3 = x_2 + y_3 = (1+2) \mod 10^9 = 3$ . 3 exists in array a.
- $x_4 = x_3 + y_4 = (3 + (-1)) \mod 10^9 = 2$ . 2 doesn't exist in array a.
- $x_5 = x_4 y_5 = (2 (-3)) \mod 10^9 = 5$ . 5 exists in array a.

#### **Time Limit**

2 seconds.
