SPEED LIMIT

Problem Description

Basri, Lim and Rama are taking a road trip during their semester break. But the odometer in their car is broken, so they don't know how many miles they have driven. Fortunately, Bill has a working stopwatch, so they can record their speed and the total time they have driven. Unfortunately, their record keeping strategy is a little odd, so they need help computing the total distance driven. You are to write a program to do this computation.

For example, if their log shows

Speed (miles/hour)	Total elapsed time in hours
20	2
30	6
10	7

this means they drove 2 hours at 20 miles per hour, then $6-2 = 4$ hours at 30 miles per hour, then $7-6=1$ hour at 10 miles per hour. The distance driven is then $(2)(20) + (4)(30) + (1)(10) = 40 + 120 + 10 = 170$ miles. Note that the total elapsed time is always since the beginning of the trip, not since the previous entry in their log.

Input

The input consists of one or more data sets. Each set starts with a line containing an integer n, ($1 \leq n \leq 10$), followed by n pairs of values, one pair per line. The first value in a pair, s, is the speed in miles per hour and the second value, t, is the total elapsed time. Both s and t are integers, ($1 \leq s \leq 90$) and ($1 \leq t \leq 12$). The values for t are always in strictly increasing order. A value of -1 for n signals the end of the input.

Output

For each input data set, print the distance driven, followed by a space, followed by the word "miles".

Sample Input Output

Sample Input	Sample Output
3 20 2 30 6 10 7 2 60 1 30 5 4 15 1 25 2 30 3 10 5 -1	170 miles 180 miles 90 miles
